Introduction

In 2022, Michigan State University researchers and Michigan dry bean producers tested 161 lines from 12 market classes of dry beans. The trial plots (Table 1) were placed in six locations across five Michigan counties: Bay, Huron, Montcalm, Sanilac, and Tuscola (two sites).

Small- and medium-seeded beans were tested in Bay, Huron, Sanilac, and Tuscola counties. Large-seeded beans were tested in Montcalm County and at the Saginaw Valley Research and Extension Center (SVREC) in Tuscola County.

This report summarizes the results of the trials. Please contact Scott Bales (phone 989-262-8550, ext. 2; email baleesco@msu.edu) with questions about the 2022 performance trials and suggestions for the 2023 trials.

Table 1. 2022 research trial conditions: The locations, grower co-operators, planting dates, nitrogen application rates and methods, total accumulated growing degree days (GDD), and total precipitation.

County	Co-operator	Planting Date	Nitrogen Rate (Lbs./A)	Nitrogen Application Method	Total GDD ^a	Total Precipitation (Inches)
Bay	Schindler Farms	June 15	50	Broadcast	1,847	11.37"
Huron	Richmond Brothers	June 8	50	2x2	1,868	5.37"
Montcalm	Rader Farms	June 10	60	Broadcast + 2x2	1,935	13.50 + irrigation
Sanilac	Stoutenburg Farms	June 3	50	Broadcast + 2x2	1,998	8.00"
Tuscola (kidney beans)	Saginaw Valley Research and Extension Center	May 31	40	Broadcast	1,960	7.57"
Tuscola (small & medium seed)	Rayl Farms	June 2	50	2x2	2,108	9.52"

Note. Weather data was retrieved from on-site weather systems reporting to LOCOMOS (Low-Cost Monitoring System) stations. All weather data is from the day of planting to harvest.

^aGrowing degree days (GDD) were calculated using the following equation: $([MAX + MIN] \div 2) - 50 = GDD$

Methods

Dry beans were seeded in four-row plots that measured 6.6' wide by 20' long, with 20" rows. Each entry was replicated four times. All trial plots were designed as randomized complete blocks (RCB). (RCB is a standard agricultural trial design in which entries are randomly assigned to groups or blocks, and the blocks are randomly repeated. The goal of the replication is to control for variables that might affect an entry's yield, such as soil nutrient levels, pest loads, and variability in soil textures.)

Trials received industry standard seed treatments, fertilization, and weed control applications at labeled rates. White mold fungicides were not applied to any location. The absence of fungicide allowed the evaluation of each entry's natural tolerance for or avoidance of white mold.

Yield data was obtained by direct harvest for small- and medium-seeded beans. Large-seeded beans were pulled by a two-row Pickett bean puller and then mechanically threshed to prevent harvest loss. Following harvest, samples were cleaned, weighed, and moisture tested.

Table 2. Soil test information from the six 2022 performance trial locations, including the percentage of organic matter, soil type, and soil pH. All macro- and micronutrients were sufficient for dry bean production.

Location	Percentage of Organic Matter	Soil Type	Soil pH
Bay	2.3	Loam	7.3
Huron	2.2	Loam	7.6
Montcalm	1.6	Loamy Sand	6.3
Sanilac	3.5	Loam	7.2
Tuscola (Kidney beans)	2.5	Clay Loam	7.7
Tuscola (Small and medium seed)	2.5	Sandy Loam	7.1

Results

Tables 3 through 12 provide agronomic information such as plant maturity, flowering date, height, lodging, and white mold tolerance. Plant maturity and flowering are rated visually in days after planting (DAP) for all locations. Lodging is rated on a scale of 1 to 5, with 1 indicating that the entry was completely erect in the field at harvest and 5 indicating that it was flat on the ground with stems and pods touching the soil surface. The percentage of white mold infection on each replication was calculated in Bay, Tuscola, and Montcalm counties:

$$(\text{number of infected plants} \div \text{total plants per stand}) \times 100 = \text{percentage of infection}$$

The tables also present each entry's yield results in pounds per acre (Lbs./A) adjusted to 18% moisture.

The combined average yield for each entry across all sites in 2022 is also included. (**Note:** If an entry was grown under different production systems [irrigated versus dry land] at different sites, the combined yield was not calculated.) When possible, two- and three-year average yields were also calculated across locations. For example, the three-year average yield of a navy bean entry (Table 3) includes data from 2020, 2021, and 2022 at four locations per year (12 site-years).

The last three rows of the agronomic and yield results tables list the trial average (mean), least significant difference (LSD), and coefficient of variation (CV), respectively, for the data in each column.

The entry with the **highest** value in each yield column is followed by two asterisks (**). Any yields listed in the same column that are not significantly different from the highest yield are noted with one asterisk. Conversely, the entry with the **lowest** white mold infection percentage is also noted with two asterisks, and any entries in that column that are not significantly different from the lowest infection percentage are marked with one asterisk. This means that if two entries in the same column are followed by either one or two asterisks, the difference in values between the entries is not statistically significant.

Table 3. Navy bean agronomic and yield results.
